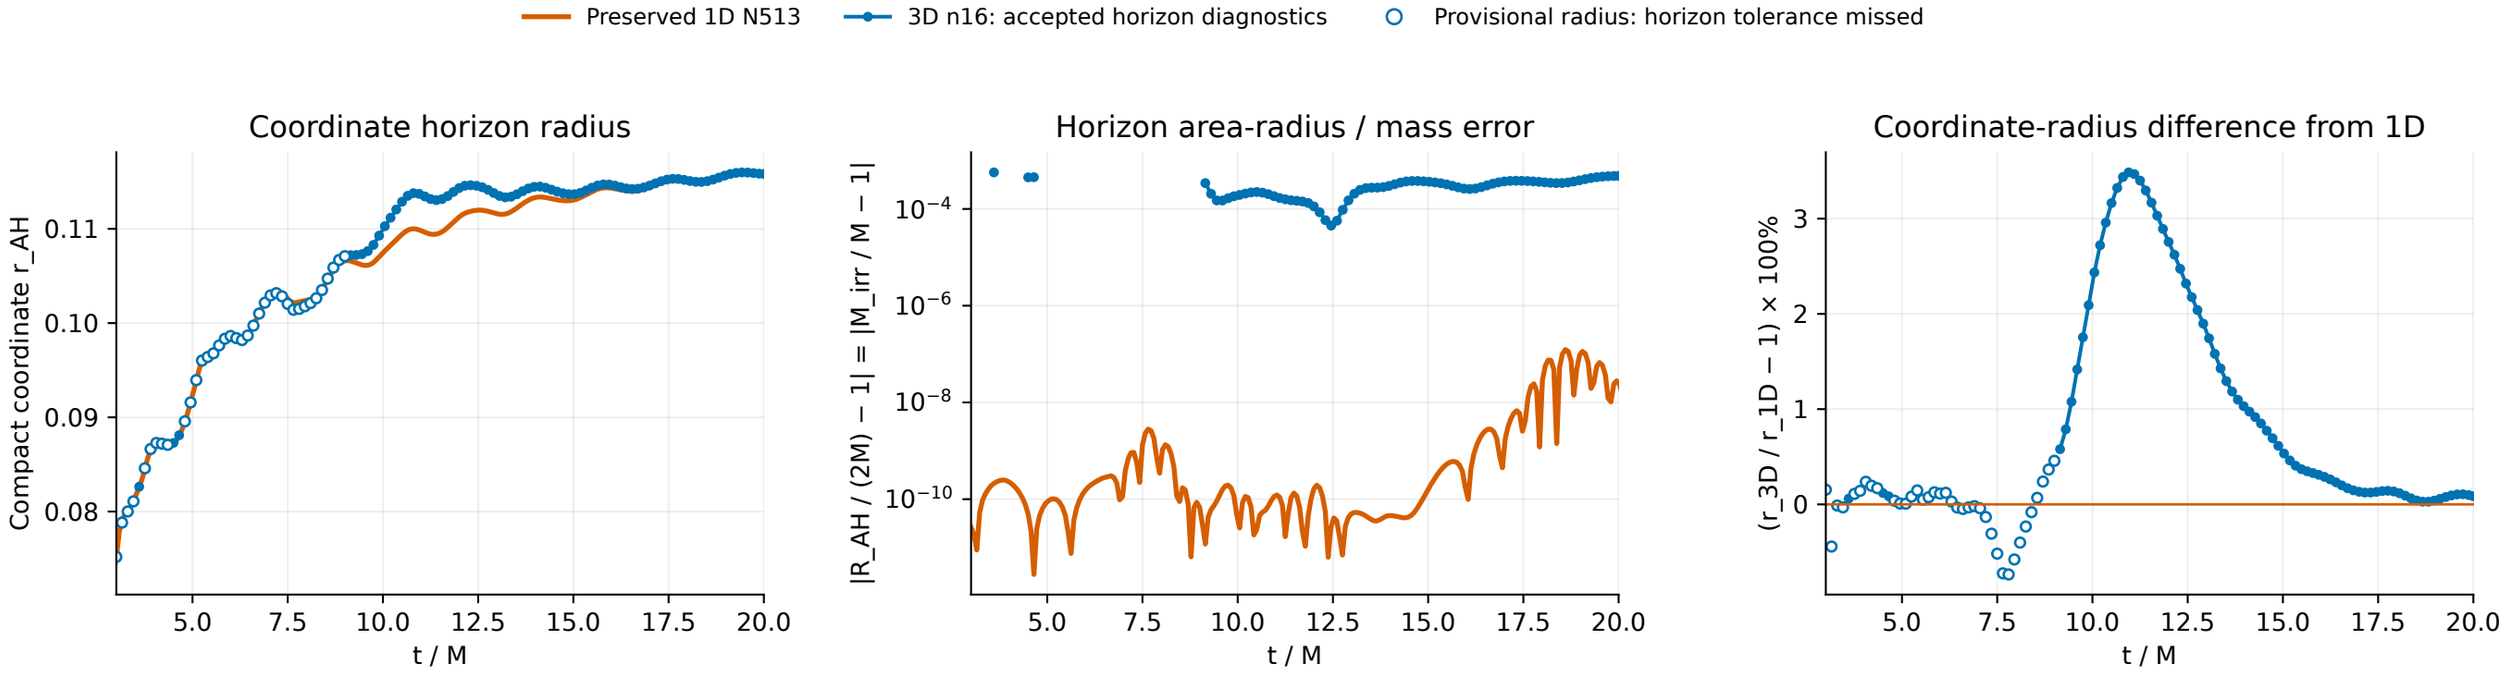
Puncture evolution to 20M: horizon comparison

3D core Δx = 0.01125; 1D Δr = 0.001953125 (5.76× finer). 3D Δt is 10.24× larger.



Direct chi/lapse continuation begins at 3M. Open circles are provisional radii; missing area diagnostics are left as gaps.

Unequal resolution and different discretizations: this is not a convergence test. Radius agreement does not prove identical outermost-root selection.
